CASE REPORT

Masked Tumor: A Rare Presentation of Struma Ovarii Disguised under Features Imitating Malignancy

Suhani Chandra1, Shraddha Shetty2, Vatsala Mallya3, Rashmi Polnaya4, Suprajna Shetty5, Cheryl Philipose6

Abstract

Aim: To present a rare case of struma ovarii in a 46-year-old lady presenting with features pointing toward malignancy.

Background: Struma ovarii is a specialized or monodermal teratoma, which is predominantly composed of mature thyroid tissue. It accounts for less than 5% of all ovarian teratomas. It is mostly benign, and malignant changes are extremely rare. Most patients are asymptomatic or may present with mild signs and symptoms. Although the vast majority are benign, they may rarely present mimicking malignancy.

Case description: A 46-year-old lady presented with a large complex abdominopelvic mass with ascites and elevated CA-125 levels, thus arising suspicion of malignancy. Postoperatively, histopathology revealed a benign struma ovarii, which was further confirmed by immunohistochemistry.

Conclusion: Struma ovarii can imitate ovarian malignancy clinically, especially if it is complex and found in combination with ascites and an elevated CA-125 level. There is paucity of literature about such cases, and hence, it makes an accurate and timely diagnosis difficult.

Clinical significance: This case is one of the very few that provide a description of an atypical presentation of a rare tumor, struma ovarii. A high level of clinical suspicion may help with better preparedness before surgery and prevent extensive laparotomies in such patients.

Keywords: Germ cell tumors: case report, Hyperthyroidism, Mature teratoma, Monodermal teratoma, Ovarian tumor, Struma ovarii.

Background

Struma ovarii is a specialized mature teratoma mostly comprising of mature thyroid tissue. The tissue of thyroid origin must make up at least 50% of the entirety to be designated as a struma ovarii. It is an exceedingly rare histopathological diagnosis and is found in just 3% of ovarian teratomas, 2% of all germ cell tumors, and less than 1% of all ovarian tumors. It is most often found associated with a mature cystic teratoma, rarely with a cystadenoma. Most cases are benign and can be managed by surgical excision. Malignant change is extremely rare.4 Ascites may be found in approximately 17% of cases, and association with elevated CA-125 is rare.5 We hereby present a case of struma ovarii that presented with misleading findings pointing toward malignancy.

Case Description

A 46-year-old lady reported to our hospital with a history of abdominal distension for the last 1 month. On per abdomen examination, a mass of approximately 10 × 8 cm was noted arising from the pelvis. It was nontender, had solid to cystic inconsistency, and was transversely mobile. On bimanual examination, a large cystic mass was felt posterior to and separate from the uterus. The ultrasonographic evaluation revealed moderate ascites and a large cystic mass of 12 × 6 cm in the pelvis with septations within. CA-125 was found to be 270. All other blood investigations were within normal limits. Total abdominal hysterectomy with B/L salpingoophorectomy with infracolic omentectomy was performed with a high degree of suspicion for malignancy. Intraoperative findings revealed gross serous ascites. A mass of 11 × 8 × 4 cm with solid and cystic components arising from the left ovary was noted and removed (Fig. 1). Histopathology report revealed a monodermal teratoma—struma ovarii, with negative fluid cytology (Fig. 2A). Thyroid transcription factor 1 (TTF-1) immunohistochemistry marker was detected to be positive, further confirming the diagnosis (Fig. 2B).

A Rare Case of Struma Ovarii

Postoperatively, the patient recovered uneventfully but later developed subclinical hypothyroidism.

Discussion

The most common ovarian germ cell neoplasms are benign mature cystic teratomas, more commonly called dermoid cysts. On histological examination, finding thyroid tissue within them is rare, but if it composes more than 50% of the mass, then the term struma ovarii is applied. It can be asymptomatic or present as a pelvic mass in the reproductive age-group with otherwise normal parameters. The proportion of patients who present with symptoms of hyperthyroidism and can be clinically diagnosed as a case of struma ovarii is very low. A combination of struma ovarii with elevated CA-125 and gross ascites has rarely been reported and thus, in our case, gave rise to clinical suspicion of malignancy. The patient was carefully evaluated keeping the possibility of a malignant tumor in mind and underwent a staging laparotomy. The histopathology, however, gave a reassuring diagnosis of struma ovarii, which was further confirmed by immunohistochemistry.

Clinically, only about 5% of struma ovarii is found to be malignant, out of which papillary carcinoma is the most frequent variant. Immunohistochemical markers such as HBME-1, CK19, and CD56 may be used to confirm malignancy. This tumor is extremely uncommon, and therefore, there is paucity of specific guidelines to outline the management of such cases.

The rarity of this tumor and its resemblance to malignancy poses a major diagnostic challenge. The presence of hyperthyroidism, ascites, pseudo-Meigs’ syndrome, and elevated tumor markers all contribute to the already perplexing task of diagnosing a struma ovarii. Identification of “struma pearl” on ultrasound might be helpful for diagnosis. Intracystic high-attenuation lesions suggestive of thyroid colloid have been seen on CT scan in some cases. The aid of MRI may also be taken. According to recent studies, thyroid scintigraphy may also be utilized for an accurate diagnosis.

Conclusion

Struma ovarii can imitate ovarian malignancy clinically, especially if it is complex and found in combination with ascites and an elevated CA-125 level. Rarely, it may be associated with overt hyperthyroidism in which case the management becomes even trickier. It is important to keep in mind struma ovarii as a differential diagnosis in such a woman who is planned for surgery because a hyperthyroid crisis can occur due to surgical stress. Preoperatively, diagnosed patients may even be offered a laparoscopic approach for management and avoid major surgeries and related morbidity. Furthermore, the thyroid gland can increase in size or subclinical or clinical hypothyroidism can follow oophorectomy. Although the presentation is often vague, a high degree of clinical vigilance and appropriate aid of imaging techniques can provide more accurate preoperative diagnosis and help prevent extensive laparotomies in such patients.

Clinical Significance

This case is one of the very few that provide a description of an atypical presentation of a rare tumor, struma ovarii. A high level of clinical suspicion and appropriate knowledge may help with better preparedness before surgery and prevent extensive laparotomies in such patients.
